No errors or problems were found.

Redirects

Internal redirects that have been linked

Optimization Tips

Video tutorial included ►

This list includes internally linked URLs that redirect to another URL on your website via a server-side [redirect](#) (status code 301).

Why you should avoid having internal links to redirecting URLs:

301 redirects are a good option if you need to change the URL of a page, or if you want to redirect multiple URLs to a single URL. However, for internal links, it is best not to link to a URL that redirects to another URL. Instead you should link directly to the destination of the redirect. This will avoid any errors if you decide to remove the redirect at some point.

Search engines like Google do follow your redirects (even if you have multiple redirects in a row), but if you use a lot of redirects, you are unnecessarily wasting the [crawling resources of the search engine bots](#). This keeps the bots busy following your redirects rather than crawling your actual page content. It can also increase [page load time](#) as each redirect requires a new request to be sent to the website server.

You can find more information about redirects [in our wiki](#) and [on the Google Search Central page](#).

What the information in this list means:

The left column ("Start URL of the redirect") shows the redirecting URL and (below it) the destination URL. The "Pages that link to a redirect" column lists all the pages that have a link pointing to the redirecting URL. If the link is located in a [canonical tag](#), [alternate link](#) or similar, you will see a note saying "Linked via canonical link, alternate link or similar".

How to fix internal redirects:

Change the links on the linking pages to point directly to the redirect's destination URL.

By clicking on the redirecting URL, you can see more details about where these links are located.

#	Start URL of the redirect	Pages that link to a redirect

Redirect loops

Redirect loops because of HTTP redirects and canonical links

Optimization Tips

Video tutorial included ►

The URLs listed here are part of a redirect loop.

What redirect loops are and why they are a problem:

Redirect loops occur when a URL redirects to itself or to a previous redirect.

For example: Page A redirects to page B. However, page B redirects back to page A.

This can happen due to wrongly configured [redirects](#) (301/302 redirects). Another reason could be pages that have another URL set as their [canonical URL](#) but the canonical URL redirects back to the other page (either via a server redirect or via a canonical link).

Redirect loops should be avoided at all costs. In theory, they redirect search engine crawlers endlessly, so that they never reach the destination of the redirect. In reality, crawlers will stop following the redirects once they realize that there's a loop. As a result, the content of URLs in this loop won't be crawled and [indexed](#). In addition to that, endless loops due to redirects also cause site visitors to receive an error message in their browser.

How to fix redirect loops:

Click on the URLs in this list to go to the "Page details" and check the redirect destination. You can click on the URL displayed there and check its redirect destination too. Repeat this step until you have a complete overview of the redirect loop. The "Links" tab of the "Page details" can also be helpful for this.

Then break the loop. For example, remove a page's redirect to itself, or fix incorrect canonical links. Also, make sure that you don't have any internal links to redirecting URLs, but link directly to the destination of the redirect.

Problems with external Links

Problems with external links that are broken or redirect to another page

Optimization Tips

Video tutorial included ►

This analysis provides an overview of problematic [external links](#) on your website.

Why you should fix problems with external links:

Linking to external sites is usually a good idea, as it adds value to your content by providing related resources for your visitors. This is also a sign of quality for search engines. After all, there are no

scientific studies or articles without references.

However, external links that point to inaccessible or redirecting pages with different content than expected can lead to a poor user experience. Therefore, you should remove them as soon as possible. Unfortunately, it is not possible to prevent problems with external links in advance, as you usually do not have any control over the content of the linked pages. However, as soon as you see any new problems here, you should check the links and update them if necessary.

You can find more best practices for external links [in our wiki](#).

What the notes in the "Problems" column mean:

- **Bad HTTP status code:** The server of the page you are linking to returns an error code when the URL is requested. You can find an overview of the meaning of the various HTTP status codes [here](#).
- **Page is down:** The server of the linked page did not respond at the time the URL was requested. Possible causes: server problems, the Seobility bot is blocked from accessing the page.
- **Redirect:** The linked page redirects to a different URL.
- **Parked domain:** The linked website is no longer online and the domain has been put up for sale.
- **Domain not connected:** The domain you are linking to is not connected to a web server and is therefore not serving any content.

How to fix these problems:

First, do a manual check of the links in this list in your browser. In this way, you can rule out that the problem was temporary or that only the Seobility bot was blocked from accessing the page.

If the link does not lead to the desired content when manually checking, you should remove or replace the link. The list shows on which pages of your site the external link is included.

Note: The results of this analysis are cached in Seobility for a few days in order to minimize access to other websites. Consequently, you may see some errors here that no longer exist.

#	URL	Problems

Canonical link errors

Canonical links that refer to broken links

Optimization Tips

Video tutorial included ►

This analysis lists pages with [canonical link](#) errors.

Why you should avoid canonical link errors:

Canonical tags signal to search engines like Google that the linked URL is the "original" version of the page and should be [indexed](#). However, if this URL is inaccessible or, for example, a page has multiple canonical tags, you make it difficult for search engines to index your content correctly. You should therefore make sure that canonical links are always clear and that the linked pages do not have any technical problems.

What the notes in the "Problem" column mean:

- **Problematic status code:** The canonical link points to a URL that returns a problematic HTTP status code (e.g. [404 error](#)). You can find an overview of the meaning and the causes of the various HTTP status codes [here](#).
- **Broken target:** The canonical link points to a "broken" or wrong target, such as an image file instead of an HTML page.
- **Canonical link markup is empty:** There is no URL in the canonical tag for this page.
- **More than one canonical link on page:** The page has more than one canonical tag, which sends conflicting signals to search engines.
- **Canonical link target is redirect:** The URL linked to in the canonical tag redirects to another URL.
- **External domain:** The URL in the canonical tag is located on an external domain. External canonical links should only be used in exceptional cases and only if there is a good reason to do this.

How to use canonical links correctly:

- Every page should have a canonical link pointing to either the original content or the page itself.
- There should be only one unique canonical link for each page.
- The URL in the canonical tag should be an accessible page that has no technical errors or redirects.

You can find more information [about canonical links in our wiki](#).

#	Page with canonical link	Problem
1.	https://www.motogo24.cz/  https://motogo24.cz/	Problematic status code
2.	https://www.motogo24.cz/upravit-rezervaci  https://motogo24.cz/upravit-rezervaci	Problematic status code
3.	https://www.motogo24.cz/kosik  https://motogo24.cz/kosik	Problematic status code
4.	https://www.motogo24.cz/?currency=CZK  https://motogo24.cz/	Problematic status code
5.	https://www.motogo24.cz/?currency=EUR  https://motogo24.cz/	Problematic status code

Alternate link errors

Problems with alternate links (links to specify alternative language or country versions of a page)

Optimization Tips

Video tutorial included ►

Here you will see problems with alternate ([hreflang](#)) links on your website.

Why alternate links are important for SEO:

If you're using different languages or regionalized content on your website, you should use alternate links to tell search engines which URL version of a page is intended for which languages and regions.

This helps search engines to display the correct version of a page in their different country searches (e.g. Google.co.uk, Google.es or Google.fr).

It also helps them understand if multiple URLs are different language/country versions of the same page, rather than [duplicate content](#). For example, if a website has different versions of a page for the US and the UK, alternate links can ensure that these two pages are not considered duplicates.

Best practices to consider when using alternate links:

- Every page that uses alternate links should also have a link to itself. For example, a page in English should also have a link to itself with `hreflang="en"`.
- Alternate links must always be set in both directions. For example, if an English page links to the French version, the French version should also link back to the English version.
- Language and country information in alternate links should use the ISO standard (e.g. "en", "en-US" or "es-US").

You can find more information on how to use alternate links correctly [in our wiki](#).

What the notes in the "Error" column mean:

- **No alternate link pointing to the page itself:** The page does not contain an alternate link to the page itself.
- **Language specified more than once:** The page contains multiple alternate links with the same language specification.
- **Link target appears more than once:** The page contains multiple alternate links with the same target URL.
- **Backlink on target not found:** An alternate link on this page points to a URL that does not link back to the page.
- **Different language for link pointing to page itself:** There is a language conflict on the page itself (for example, if the alternate link to the page itself does not match the [lang attribute](#)).

Click "Details" to get more information about the specific problem.

For an overview of possible hreflang tag issues and how to fix them, check out our [blog post](#).

#	URL	Error
1.	https://www.motogo24.cz/jak-pujcit/prevzeti	No alternate link pointing to the page itself
